Analytical Dashboard: OLAP Demonstration Prompts

Presentation–Time OLAP Narratives

E1. GC leaderboard with contextual descent. Begin from the overall General Classification, ordered by the lowest cumulative $\sum$adjusted_time. Follow a chosen contender down to the stage grain to surface the single day that most altered their GC standing, framing it as a pivotal moment in their race.

E2. A stage in focus. Treat one stage as a vignette: present the leading finishers with their adjusted times, riders, teams, origins and destinations, distance, and stage type. Reframe the view to a team perspective to reveal which squads populated the top ten on that day.

E3. Team burden and contribution. Roll up each team's aggregate adjusted time over the event, then open the aggregation to reveal which riders carried the time load and how their per-stage profiles shaped the team's outcome.

E4. Parallel classifications. Place side-by-side a rider's GC rank and their Young Rider GC rank (with an age filter anchored at race start). Introduce a *mountain-stage GC proxy* by accumulating adjusted time only on "Mountain" stages, and narrate where the proxy diverges from overall GC.

E5. Mountain contours. For riders, surface two mountain-specific signals: podium frequency on Mountain stages and mean time gap to the stage winner on that terrain; allow a return to the daily traces that produced these summaries.

E6. Speed as a simple ratio. For riders and teams, chart a stage-type profile using the proxy length/time across Flat, Hilly, Mountain, and ITT. Emphasize who appears to gain when the terrain shifts away from Flat/Hilly toward Mountain.

E7. Bonuses, penalties, and counterfactuals. Lay out cumulative bonuses and penalties per rider; then replay the GC leaderboard under counterfactual toggles (first removing bonuses, then penalties) to illuminate movements into and out of the top ten.

E8. Participation by nation. Summarize nations by their presence—count of teams and count of riders—then open the roll-up to list the riders and their associated teams for a chosen country.

E9. National outcomes (within available data). For each nation, note the best GC rank achieved by its riders and tally wins/podiums; keep the pathway back to the underlying stages and athletes clear.

E10. Temporal GC storyline. Trace cumulative adjusted time after each stage for the principal GC actors as a line narrative; mark Mountain stages and annotate inflection points where standings reshuffle, with rider/team filters guiding the lens.

E11. Against the clock. Within the time-trial context, surface the inventory of ITT stages and present their essentials—date, distance, and winner—as a compact catalogue.

E12. Consistency near the front. From the space of high finishes, identify the riders who most often appear in the top ten; accompany the summary with the list of contributing stages, their ranks, and stage types.

E13. Depth of squads. At the rider grain, portray team depth via distinct rider counts, highlighting squads with the broadest rosters and providing a doorway to their full rider lists and countries.

E14. Top-ten intensity by team. Aggregate top-ten presences at the team level and, where helpful, break them down by stage type; pair the totals with links back to the specific stages and riders involved.

E15. The long day. Sort stages by distance to spotlight the longest route, giving its name/date, type, and start/finish locations; complement the overview with the set of leading finishers and their adjusted times.
